

Manual Software RED-Scope V1.0

(PC software for Microsoft® Windows® 7, 8, 10)

for sensors of RED series

This manual describes the installation of the PC software for the sensors of RED series. As a support for commissioning of the sensor this manual explains the functional elements of the Windows® user interface.

The edge detectors of RED series primarily are designed for detecting and counting edges. These may be e.g. newspapers, single sheets, cardboard boxes, sheet metals, wires, lamellas, welds, rotor blades, etc.

In its optimum operating range (e.g. 80 mm when RED-80-...) sheet edges starting from 0.1 mm are reliably detected.

The sensor is characterised by a high scanning frequency and by its ability to automatically adjust itself to differently bright and dark, as well as slow and fast objects; with a minimally set output pulse length (adjustable via software) it reaches a switching frequency of 10 kHz.

Furthermore the sensor can be used for almost all conceivable applications by selecting optimised software algorithms.

The RED sensor allows highly flexible signal acquisition. The sensor, for example, can be operated in alternating-light mode (AC mode), which means the sensor is not influenced by external light, or in constant-light mode (DC mode), which provides outstanding high-speed sensor operation. With the stepless adjustment of the integrated light source, the selectable gain of the receiver signal, and an INTEGRAL function the sensor can be adjusted to almost any surface.

A micro-controller performs 12-bit analog/digital conversion of the analog signal, which allows recording and evaluation of the signal. Furthermore the RED sensor offers various options for intelligent signal processing such as e.g. dirt accumulation compensation.

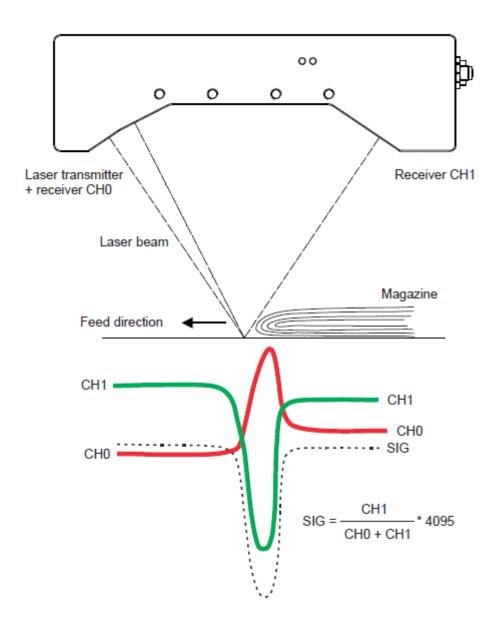

Parameters and measurement values can be exchanged between PC and sensor either through RS232 or Ethernet (using an Ethernet adaptor). Through the interface all the parameters can be stored in the non-volatile EEPROM of the sensor.

The PC software facilitates the parameterisation, diagnostics, and adjustment of the sensor system (oscilloscope function). The software furthermore provides a data recorder function that automatically records data and stores them on the hard disk of the PC.

When parameterisation is finished, the sensor continues to operate with the current parameters in STAND-ALONE mode without a PC.

The laser sensors of RED series comprise a laser transmitter (laser diode, λ =670 nm) and two receivers. As shown in the picture below, the laser beam is focused at an angle onto the edge (of the magazine) opposite to the direction of feed. When an edge arrives, it blocks the beam path to receiver CH1, whereas the signal at receiver CH0 slightly increases due to the more favourable angle of impingement! The standardised value of SIGNALS CH0 and CH1 is used as the starting signal SIG for all the further algorithms of the sensor.

The evaluated signal can be output via a voltage output or via a current output. With the help of the software, different evaluation modes for the analogue signal can be selected.

The state of the output signal is output via 2 digital outputs depending on the evaluation mode.

A digital input allows external "teaching" of the sensor.

Another input enables a "freezing" of the analog output signal with a positive signal edge.

1 Installation of the RED-Scope software

The following requirements must be fulfilled for successful installation of the RED-Scope software:

- Microsoft® Windows® 7, 8, 10
- IBM PC AT or compatible
- VGA graphics
- · Microsoft-compatible mouse
- CD-ROM drive
- Serial RS232 interface at the PC or USB slot
- Cable cab-las4/PC for the RS232 interface or cab-4/USB (or cab-4/ETH) for USB slot

The RED-Scope software can only be installed under Windows. Windows must therefore be started first if it is not yet running.

Please install the software as described below:

- 1. The software can be installed directly from the installation CD-ROM. To install the software, start the SETUP program in the INSTALL folder of the CD-ROM.
- 2. The installation program displays a dialog and suggests to install the software in the C:\"FILENAME" directory on the hard disk. You may accept this suggestion with OK or [ENTER], or you may change the path as desired. Installation is then performed automatically.
- 3. During the installation process a new program group for the software is created in the Windows Program Manager. In the program group an icon for starting the software is created automatically. When installation is successfully completed the installation program displays "Setup OK".
- 4. After successful installation the software can be started with a left mouse button double-click on the icon.

2 Operation of the RED-Scope software

Please read this chapter first before you start to adjust and parameterise the sensor system.

When the RED-Scope software is started, the following window appears on the Windows interface:

The window size and position will be the same as when the software was last closed. A double-click with the right mouse button e.g. under the minimise symbol places the window centrally in its original size.

If a connection is not established automatically, e.g. if no sensor is connected, the software can be run in OFFLINE mode. In offline mode it only is possible to exchange parameters with a file on a storage medium, which often is helpful for the purpose of analysing parameter files.

If a sensor is connected and a connection still cannot be established, either the SCOPE version (program at the PC) and the firmware version (program in the sensor) do not match, or the interface to the sensor must be correctly configured.

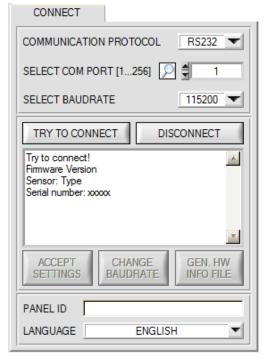

If different Scope and firmware versions should be the problem, please get the Scope version that matches the firmware from your supplier.

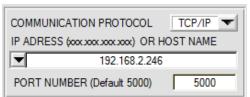

The interface configuration is described in the CONNECT tab chapter.

Pressing the right mouse button on an individual element will call up a short help text.

2.1 Tab CONNECT

CONNECT:

Pressing the **CONNECT** tab opens a window for selecting and configuring the interface.

The **COMMUNICATION PROTOCOL** function field is used for selecting either an **RS232** or a **TCP/IP** protocol.

If **RS232** is selected, a port from 1 to 256 can be selected with **SELECT COM PORT**, depending on which port the sensor is connected to. The sensor operates with a set baudrate that can be modified with **CHANGE BAUDRATE** (see below). The sensor and the user interface both must operate with the same baudrate.

At the user interface the baudrate is set with **SELECT BAUDRATE**. If after starting the software should not automatically establish a connection, the correct baudrate can be found with **SELECT BAUDRATE**.

If an adaptor is used, the **COM PORT** number can be determined by way of the hardware manager in the system control panel.

A click on the magnifier symbol opens a list with all the possible COM ports in the display.

An RS232 to Ethernet adaptor (cab-4/ETH) is needed if the sensor should communicate through a local network. With this adaptor a connection to the sensor can be established using the TCP/IP protocol.

Parameterisation of the **cab-4/ETH** adaptor (assigning of IP address, baudrate setting, ...) can be done with the **SensorFinder software** that is available free of charge on the internet.

In order to establish a connection to the adaptor, its IP address or HOST name must be entered in the field IP ADDRESS (xxx.xxx.xxx.xxx) OR HOST NAME. The DROP DOWN menu (down arrow) shows the last 10 IP addresses that were used. An address from this list can be directly selected by clicking on the respective item. The DROP DOWN list is saved and is thus always available when the software is closed.

The PORT NUMBER for the cab-4/ETH adaptor is set to 5000 and must not be changed.

When you press the **TRY TO CONNECT** button, the software tries to establish a connection with the set parameters. The communication status is shown in the display field. If the sensor answers with its FIRMWARE ID, the set connection type can be accepted by pressing **ACCEPT SETTINGS**. You will then be returned to the **PARA** tab. If you get a **TIMEOUT** message, the software could not establish a connection to the sensor. In this case please check if the interface cable is correctly connected, if the sensor is supplied with power, and if the set parameters are correct.

If a connection has been accepted by pressing **ACCEPT SETTINGS**, the software starts automatically with these settings when called the next time.

DISCONNECT disconnects the connection between sensor and PC. The software then switches to OFFLINE mode, where it is only possible to exchange parameters with a file on a storage medium.

Under **PANEL ID** a designation can be entered that will be displayed at various positions in the program window and will be saved in various files (e.g. record file).

The **LANGUAGE** selection field can be used to set the language in which the individual control elements on the user interface are represented. The language also applies to the help function that can be called up with the right mouse button.

Please note:

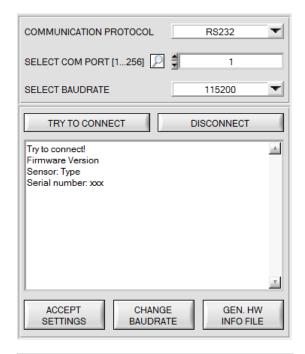

The stable function of the interface is a basic prerequisite for measured value transfer from the PC to the sensor.

Due to the limited data transfer rate through the serial RS232 interface only slow changes of the raw signals at the sensor front end can be observed in the graphic output window of the PC.

For maintaining maximum switching frequency at the sensor data communication with the PC must be stopped (press the STOP button).

The baudrate for data transfer through the RS232 interface can be set by means of the **SELECT BAUDRATE** drop down menu and **CHANGE BAUDRATE** function field.

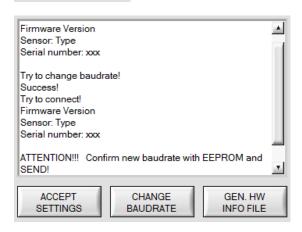

If the baudrate should be changed, a connection must first be established by clicking on **TRY TO CONNECT**.

The **CHANGE BAUDRATE** button will then be active.

Now a new baudrate can be selected under **SELECT BAUDRATE**.

A click on **CHANGE BAUDRATE** sends the new baudrate information to the sensor.

When the new baudrate information has been successfully sent, the sensor operates with the new baudrate. A window will pop up, prompting you to select **EEPROM** and then to press **SEND**. After a hardware reset the new baudrate only will be used when **EEPROM** and **SEND** have been pressed.

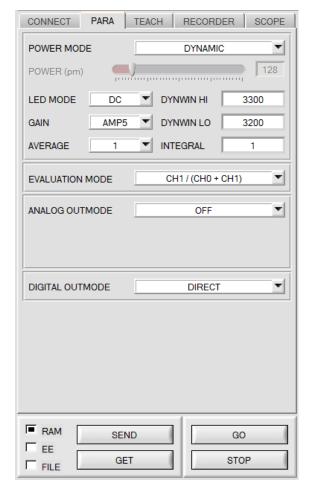

A click on **ACCEPT SETTINGS** saves the current interface settings, which will then be automatically set when the software is restarted.

A click on the **GEN. HW INFO FILE** generates a file in which all the important sensor data are stored in encrypted form. This file can be sent to the manufacturer for diagnostic purposes.

2.2 Tab PARA, button SEND, GET, GO, STOP

PARA:

Pressing the **PARA** tab opens a window for setting the sensor parameters.

ATTENTION!

A change of the parameter function groups only becomes effective at the sensor after actuation of the SEND button in the MEM function field!

SEND [F9]:

When the **SEND** button is clicked (or shortcut key button F9 is pressed), all the currently set parameters are transferred between PC and sensor. The target of the respective parameter transfer is determined by the selected button (**RAM**, **EEPROM**, or **FILE**).

GET [F10]:

The currently set values can be interrogated from the sensor by clicking on the **GET** button (or with shortcut key button F10). The source of data exchange is determined by the selected button (**RAM**, **EEPROM**, or **FILE**).

RAM:

The **RAM** is a **volatile** memory in the sensor's microcontroller, i.e. when the power at the sensor is turned off, these parameters will be lost again.

The sensor always operates with the parameters in its RAM.

If the **RAM** option is selected, a click on **SEND** writes the current parameters to the sensor's **RAM** memory, and a click on **GET** reads the parameters from the sensor's **RAM** memory.

EEPROM:

The **EEPROM** is a **non-volatile** memory in the sensor's micro-controller. When the power at the sensor is turned off the parameters in the **EEPROM** will not be lost. When power is turned on again, the parameters are loaded from the **EEPROM** to the **RAM** memory. Figuratively speaking the **EEPROM** thus is a level lower than the **RAM**. Data exchange between **PC** and **EEPROM** automatically is performed through the **RAM** memory, which means that parameters that are written to the **EEPROM** automatically are also written to the **RAM**, and data that are read from the **EEPROM** automatically are also read to the **RAM**.

If the **EEPROM** option is selected, a click on **SEND** writes the current parameters to the sensor's non-volatile **EEPROM** memory, and a click on **GET** reads the parameters from the sensor's **EEPROM**.

The **RAM** memory should always be used for parameterising the sensor. When suitable parameters have been found for the respective application, these parameters must be written to the sensor's **EEPROM** so that after restarting the sensor these parameters can be loaded from the **EEPROM** into the **RAM** memory.

FILE:

After pressing **SEND**, the current parameters can be written to a selectable file on the hard disk. With **GET** parameters can be read from such a file. When the **SEND** or **GET** button is pressed, a dialog box opens for selecting the desired file.

TIP! Once suitable parameters have been found for a certain application, these should always be saved in a file on the PC.

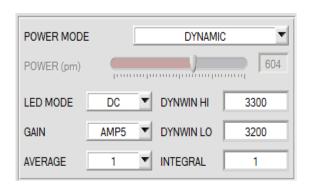

GO [F11]:

A click on this button starts data transfer from the sensor to the PC through the serial RS232 interface.

STOP [F12]:

A click on this button stops data transfer from the sensor to the PC through the serial RS232 interface.

POWER MODE:

In this function field the operating mode of automatic power correction at the transmitter unit (transmitter LED) can be set.

STATIC:

The transmitter power is constantly kept at the value set with the **POWER [pm]** slider. The **POWER** can be set with the slider or by entering a value in the edit-box. A value of 1000 means full intensity at the transmitter unit, a value of 0 sets the lowest intensity at the transmitter.

DYNAMIC:

The LED transmitter power is dynamically controlled in accordance with the amount of radiation that is diffusely reflected from the object. By using the intensities measured at the receivers the automatic control circuit attempts to adjust the transmitter power in such a way that the dynamic range, which is determined by **DYN WIN LO** and **DYN WIN HI**, is not exceeded (recommended operation mode).

LED MODE:

This item serves for setting the control mode for the integrated light source of the sensor.

DC: In this mode the sensor operates extremely fast. Unfortunately the sensor is somewhat sensitive to extraneous light in DC mode, but if the extraneous light source does not directly shine into the sensor's receiver, the signal only is influenced to a very small extent.

AC: In this mode the sensor is insensitive to extraneous light, which is achieved by "modulating" the integrated light source, i.e. by turning the light on and off. The extraneous content in the signal is determined in off status and is simply subtracted from the on status.

GAIN

This item is used for setting the gain of the receiver directly in 8 different gain stages (AMP1 to AMP8). **GAIN** should be set such that with a medium **POWER** value the sensor operates in its dynamic range.

In addition, AMP 1 2 3 4, AMP 5 6 7 8, AMP 1 3 5 7 and AMP 2 4 6 8 can be set for GAIN.

This makes it possible to set different amplification factors at the receiver with inputs IN0 and IN1.

This means that IN0 and IN1 are no longer available for other options.

Depending on GAIN and on the state of inputs IN0 and IN1 the following amplification factors are possible.

IN1	IN0	AMP 1 2 3 4	AMP 5 6 7 8	AMP 1 3 5 7	AMP 2 4 6 8
0	0	1	5	1	2
0	1	2	6	3	4
1	0	3	7	5	6
1	1	4	8	7	8

In AC mode, GAIN directly influences the scan frequency. The current scan frequency is displayed in the SCOPE tab

AVERAGE:

This function field is used for adjusting the number of scanning values (measurement values) over which the raw signal measured at the receiver is averaged. A higher **AVERAGE** default value reduces noise of the raw signals at the receiver unit and there will be a decrease of the maximal available switching frequency of the sensor

INTEGRAL:

This function field is used to set the number of scan values (measurement values) over which the raw signal measured at the receiver is summed up. This integral function allows the reliable detection even of extremely weak signals. A higher **INTEGRAL** value increases the noise of the raw signals of the receiver unit, and simultaneously decreases the maximum achievable switching frequency of the sensor.

INFO

The POWER slider is only effective in the POWER MODE = STATIC.

DYN WIN LO and DYN WIN HI are only effective in POWER MODE = DYNAMIC.

EVALUATION MODE:

This parameter determines how the two channels **CH0** and **CH1** are evaluated.

CH0: CH0 is directly used as EVALUATION SIGNAL.

CH1: CH1 is directly used as EVALUATION SIGNAL.

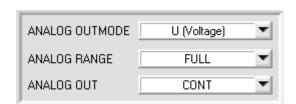

CH0-CH1: The EVALUATION SIGNAL is calculated from CH0-CH1.

CH1-CH0: Das EVALATION SIGNAL is calculated from CH1-CH0.

(CH0+CH1)/2: The EVALUATION SIGNAL is calculated from (CH0+CH1)/2.

CH0/(CH0+CH1): The EVALUATION SIGNAL is calculated from (CH0*4095)/(CH0+CH1).

CH1/(CH0+CH1): Das EVALATION SIGNAL is calculated from (CH1*4095)/(CH0+CH1).

The **EVALUATION SIGNAL** is used for outputting an analog signal

It is acquired with a resolution of 12 bit and therefore may have values between 0 and 4095.

ANALOG OUTMODE:

This function field determines the operating mode of the analog output.

OFF:

No analog signal is output.

U (Voltage):

The **EVALUATION SIGNAL** is provided at the analog output as a voltage of 0 – 10V.

I (Current)

The **EVALUATION SIGNAL** is provided at the analog output as a current of 4 – 20mA.

ANALOG RANGE:

This function field determines how and in which range the sensor outputs the **EVALUATION SIGNAL** in analog form

FULL:

EVALUATION SIGNAL is output in its full value range of 0-4095 as an analog signal.

MIN-MAX while IN0:

As long as input IN0 is HI, a maximum and minimum **EVALUATION SIGNAL** value are determined in the sensor. After IN0 drops, the analog signal is fully output (0-10 V and/or 4-20mA) within this **MIN-MAX** range.

ANALOG OUT:

This function field is used to determine when the sensor outputs the analog signal. .

CONT: The analog signal is output continuously.

RISING EDGE of IN1: The analog signal only is output when there is a positive edge at IN1.

DIGITAL OUTMODE:

This function field is used to determine the operating mode of digital outputs **OUT0** and **OUT1** when the

tolerance threshold is **exceeded**. Depending on **OUTMODE** and **THRESHOLD MODE** the status of **OUT0** and **OUT1** is as follows:

	THRESHOLD MODE LOW and HI	THRESHOLD MODE WIN				
OUTMODE OFF	OUT0=0 VDC OUT1=0 VDC	OUT0=0 VDC OUT1=0 VDC				
OUTMODE DIRECT	OUT0=0 VDC (OUT0=+24 VDC) if SIG is below the switching threshold OUT0=+24 VDC (OUT0=0 VDC) if SIG is above the switching threshold	OUT0=0 VDC if SIG is outside the tolerance window OUT0=+24 VDC if SIG is within the tolerance window OUT1=0 VDC if SIG is lower than the tolerance window OUT1=+24 VDC if SIG is higher than the tolerance window				
OUTMODE INVERSE	OUT0=+24 VDC (OUT0=0 VDC) if SIG is below the switching threshold OUT0=0 VDC (OUT0=0+24VDC) if SIG is above the switching threshold	OUT0=0 VDC if SIG is within the tolerance window OUT0=+24 VDC if SIG is outside the tolerance window OUT1=0 VDC if SIG is higher than the tolerance window OUT1=+24 VDC if SIG is lower than the tolerance window				

On the user interface the respective status of outputs is visualised by way of the OUT0 and OUT1 LEDs.

2.3 Tab TEACH

When the GO button is pressed, data transfer from the sensor to the PC is started.

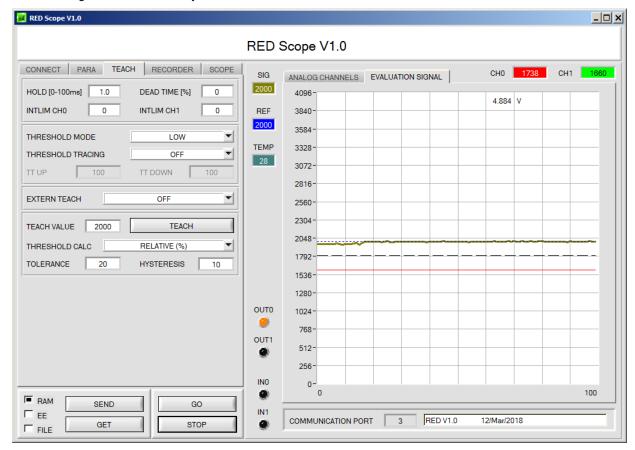

The analog signal **SIG** is shown in a graph and in a numerical display.

Using the **TEACH** button is the easiest method for "teaching" an analog signal.

With a click on the TEACH button the current SIG value is accepted as the TEACH VALUE.

With a click on SEND the TEACH VALUE becomes the new reference value REF.

The switching threshold and the hysteresis threshold are then set based on REF.

HOLD:

The sensor operates with minimum scanning times in the magnitude of less than $10\mu s$. Entering a suitable value in the **HOLD** edit box sets a pulse lengthening of up to 100 ms at the sensor's digital output. This allows a PLC to reliably detect short changes of switching states.

DEAD TIME [%]:

The dead time function can best be explained by way of an example.

Because of the application the sensor provides a regular switching signal of 100ms. These 100ms are interpreted as 100%. If a **DEAD TIME** of 20% is set, the sensor is "dead" for 20% after every switching signal. It ignores any fault that occurs within 20ms after the last switching process, and consequently also does not switch. For example this allows the correct detection of unclear edges without the sensor providing multiple pulses.

If the speed changes from 100ms to 200ms, 20ms dead time will become 40ms due to percentage calculation, which is why this is referred to as a dynamic dead time.

It is advisable to use a dead time, if multiple pulses cannot be suppressed with a suitable HYSTERESIS.

DEAD TIME [%] = 0 deactivates the dead time.

INTLIM:

These parameters are used for background suppression.

If CH0 is less than INTLIM CH0 or CH1 is less than INTLIM CH1, the outputs are switched as if SIG was 0.

INTLIM CH0 and INTLIM CH1 are very helpful when SIG is viewed in a normed way, i.e. when EVALUATION MODE CH0/(CH0+CH1) or CH1/(CH0+CH1) is selected.

If in this mode the sensor looks into a "void", there will be very low values for **CH0** and **CH1** due to electronic noise or reflections.

Based on calculation these values may cause a SIG value between 0 and 4095.

The outputs therefore would switch permanently.

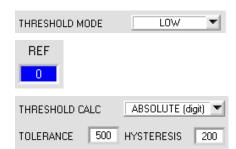

Example with SIG = (CH0*4095)/(CH0+CH1) and a signal noise of e.g.

CH0=12, CH1=4 → SIG = 3071

CH0=4, CH1=12 → SIG = 1023

If, for example, the threshold was 2000, the sensor would switch permanently.

If you, for example, select a value of 50 for **INTLIM CH0** and/or **INTLIM CH1**, the sensor outputs the state as if SIG = 0.

THRESHOLD MODE:

In this function field one of the possible positions of the switching threshold and hysteresis threshold with respect to the reference value **REF** can be selected.

The reference value is learned either by means of the software or through the external input IN0. Furthermore, automatic threshold tracing can be activated with **THRESHOLD TRACING**, which means that **REF** is cyclically re-determined.

Based on **REF** and with the help of **TOLERANCE** and **HYSTERESIS** the switching threshold and the hysteresis threshold are calculated differently with **THRESHOLD MODE LOW**, **HI** and **WIN**.

If THRESHOLD CALC = ABSOLUTE(digit) is selected, the thresholds are calculated absolutely in digits to REF, i.e. TOLERANCE and HYSTERESIS are directly added to or subtracted from REF.

If **THRESHOLD CALC = RELATIVE(%)** is selected, the thresholds are calculated relatively to **REF**=100%, i.e. **TOLERANCE** and **HYSTERESIS** are relatively added to or subtracted from **REF**.

The different lines in the following graphic windows have the following meaning:

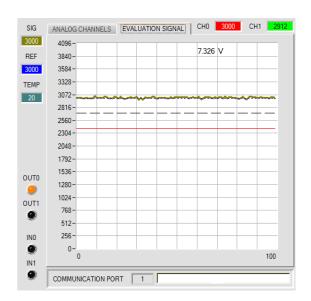

Green line = current measurement value SIG

Blue dotted line = reference value REF

Red line = switching threshold

Black dashed line = hysteresis threshold

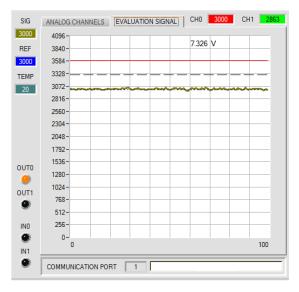

THRESHOLD MODE = LOW:

Switching threshold = REF - TOLERANCE Hysteresis threshold = REF - HYSTERESIS

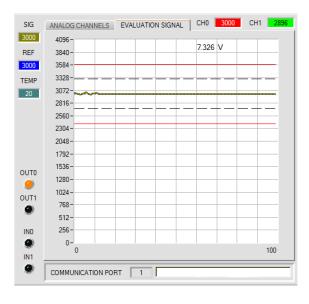

When the current measurement value **SIG** falls below the switching threshold, the digital output **OUT0** is set to error. When the current measurement value rises above the hysteresis threshold again, the error output is reset again.

THRESHOLD MODE = HI:

Switching threshold = REF + TOLERANCE Hysteresis threshold = REF + HYSTERESIS

When the current measurement value **SIG** rises above the switching threshold, the digital output **OUT0** is set to error. When the current measurement value falls below the hysteresis threshold again, the error output is reset again.

THRESHOLD MODE = WIN:

Upper switching threshold = REF + TOLERANCE Upper hysteresis threshold = REF + HYSTERESIS

Lower switching threshold = REF - TOLERANCE Lower hysteresis threshold = REF - HYSTERESIS

The switching thresholds form a symmetrical tolerance band around the current reference value. When the current measurement value **SIG** leaves this tolerance band, the digital output **OUT0** is set to error.

The error output is reset again when the current measurement value lies below/above the hysteresis threshold again.

Depending on **OUTMODE**, the output **OUT1** is set or reset when the signal leaves the tolerance window upwards or downwards.

THRESHOLD TRACING:

Automatic threshold tracing can be activated in this function field. Actually the reference value **REF** cyclically follows a changing **SIG** value.

Switching threshold and hysteresis threshold then are set based on **REF**.

Generally this is referred to as threshold tracing.

OFF: Automatic threshold tracing is deactivated.

ON TOL and **ON CONT:** Automatic threshold tracing is activated. The current reference value **REF** is cyclically adapted if the current **SIG** value decreases, e.g. due to increasing dirt accumulation.

With ON TOL tracing is performed when the current signal lies within the tolerance.

With **ON CONT** tracing is performed continuously.

TT UP and TT DOWN: In this function field a time constant for the speed of automatic threshold tracing can be set. TT UP (THRESHOLD TRACING UP): When the current SIG value rises, REF is increased by one digit with the set delay.

TT DOWN (THRESHOLD TRACING DOWN): When the current SIG value falls, REF is decreased by one digit with the set delay.

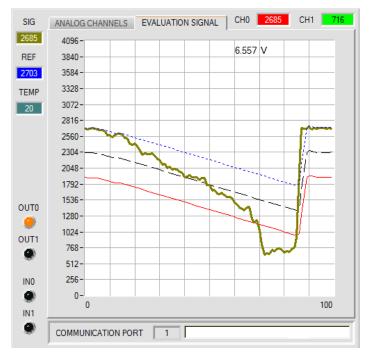

A value between 0 and 60000 can be selected for TT UP and TT DOWN.

One increment means a delay of 100 microseconds. However, tracing cannot be faster than the scan frequency that can be achieved with **AVERAGE**.

Value 0: Minimum time delay, fastest tracing.

Value 60000: Maximum time delay, slowest tracing.

The calculation of the switching thresholds depends on THRESHOLD MODE (see THRESHOLD MODE).

In this example a value of 50 was specified for **TT DOWN**. This means that downward threshold tracing is performed at a relatively slow speed. In the chart this can be clearly seen in the blue reference line.

The measurement value **SIG** falls relatively fast, compared to this the reference value **REF** follows much slower. This is a typical case that occurs when increasing dirtying of the sensor must be compensated.

With **ON TOL**, threshold tracing is stopped when the current measurement value falls below the switching threshold. When **SIG** rises above the hysteresis threshold again, threshold tracing becomes active again. In this example upward threshold tracing is fast because a small value was specified for **TT UP**.

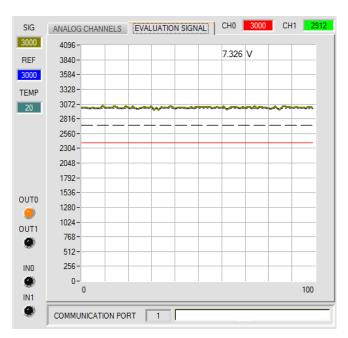

EXTERN TEACH:

This function field is used to specify how sensor "teaching" should be performed.

EXTERN TEACH OFF ▼ TEACH VALUE 3000 TEACH

EXTERN TEACH = OFF:

Using the **TEACH** button is the easiest method for "teaching" an analog signal.

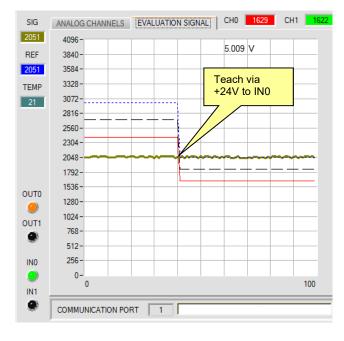

With a click on the **TEACH** button the current **SIG** value is accepted as the **TEACH VALUE**.

With a click on **SEND** the **TEACH VALUE** becomes the new reference value **REF**.

The switching threshold and the hysteresis threshold are then set based on **REF**.

The **TEACH** button is not active if either **EXTERN TEACH** or **THRESHOLD TRACING** is not **OFF**.

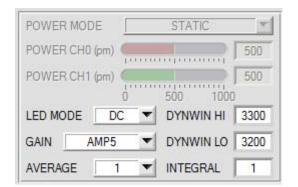

EXTERN TEACH = DIRECT:

When there is a positive edge at input IN0, the current **SIG** value becomes the new reference **REF**.

The switching threshold and the hysteresis threshold are then set based on **REF**.

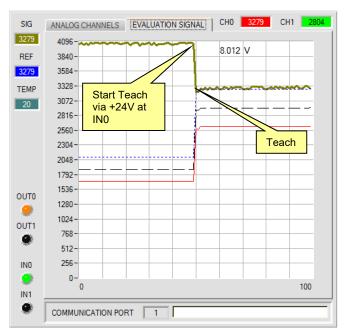

The new reference **REF** only is saved in the sensor's **RAM** and not in its **EEPROM**.

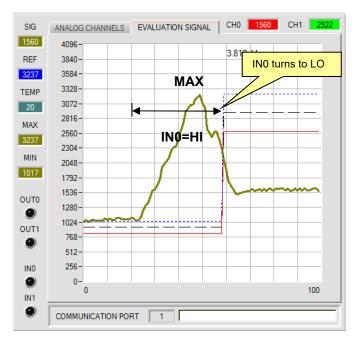

EXTERN TEACH = DYN:

POWER MODE automatically is set to **STATIC** and like **POWER** is not active with **EXTERN TEACH = DYN**.

EXTERN TEACH = DYN:

POWER MODE is automatically set to **STATIC** and like **POWER** is inactive with **EXTERN TEACH = DYN**.

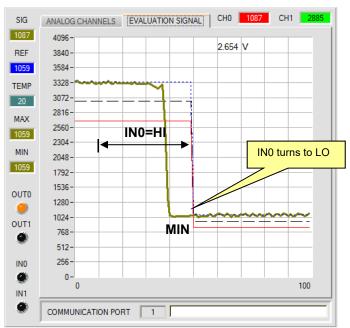

EXTERN TEACH = MAX:

While input IN0=HI (+24V), the maximum **SIG** value is determined and becomes the new reference **REF** when IN0 changes to low.

The switching threshold and the hysteresis threshold are then set based on **REF**.

The new reference **REF** only is saved in the sensor's **RAM** and not in its **EEPROM**.

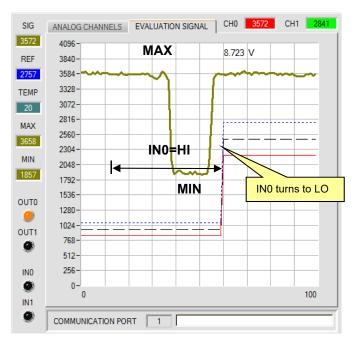

EXTERN TEACH = MIN:

While input IN0=HI (+24V), the minimum **SIG** value is determined and becomes the new reference **REF** when IN0 changes to low.

The switching threshold and the hysteresis threshold are then set based on **REF**.

The new reference **REF** only is saved in the sensor's **RAM** and not in its **EEPROM**.

EXTERN TEACH = (MAX+MIN)/2:

While input IN0=HI (+24V), the maximum and minimum **SIG** values are determined.

When INO changes to low, the new reference **REF** is set exactly between MAX and MIN.

The switching threshold and the hysteresis threshold are then set based on **REF**.

The new reference **REF** only is saved in the sensor's **RAM** and not in its **EEPROM**.

2.4 Graphic display elements

The software provides various display elements and a graphic window for the visualisation of all the data that are important for parameterisation. The individual display elements and the graph are explained in the chapter below.

CH0 and CH1:

These displays show the analog signals of the individual channels.

The graph under the **ANALOG CHANNELS** tab shows the values as lines. **SIG:**

This display shows the measurement value that is determined from **CH0 and CH1**. The graph under the **EVALUATION SIGNAL** tab visualises **SIG** as a line.

RFF:

This display shows the current reference value. This value is the basis for the calculation of switching threshold and hysteresis threshold.

If THRESHOLD TRACING and EXERN TEACH are set to OFF, the TEACH VALUE is the reference value. If THRESHOLD TRACING is set to ON, automatic threshold tracing is activated. The current reference value REF is cyclically adapted to compensate a lowering of the current SIG value, e.g. due to increasing dirt accumulation.

Depending on the setting of **EXERN TEACH** the reference **REF** can also be taught through input IN0 with various methods.

In the graph the reference value **REF** is represented as a blue line.

MAX and MIN:

If with **EXTERN TEACH** or **ANALOG RANGE** a search for a minimum and/or maximum **SIG** value is necessary, these values are shown in these displays.

The two displays only are active when they are needed.

TEMP

44

TEMP:

This display shows the temperature prevailing in the sensor housing.

The display **DOES NOT** show degrees Centigrade or Fahrenheit.

OUT0 und OUT1:

These LEDs visualise the physical status of outputs OUT0 and OUT1.

When the LED is black, the output value is 0V.

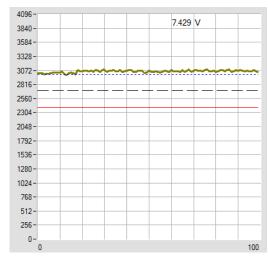

When the LED is orange, the output value is +24V.

IN0 and IN1:

These LEDs visualise the physical status of inputs IN0 and IN1.

When the LED is black, the input value is 0V.

When the LED is green, the input value is +24V.

GRAPH:

The graphic display window shows the switching threshold (red line), the hysteresis threshold (black dashed line), the reference value **REF** (blue dotted line), and the current analog signal **SIG** (green line) depending on the set parameters.

In the graph of this example the parameter settings are as follows:

THRESHOLD MODE = LOW, THRESHOLD TRACING = OFF

EXTERN TEACH = OFF

TEACH VALUE = 3000 (→ REF=3000)

THRESHOLD CALC = RELATIVE (%)

TOLERANCE = 20

HYSTERESIS = 10

This results in a switching threshold of **TEACH VALUE** minus **TOLERANCE** (red line), and in a hysteresis threshold of **TEACH VALUE** minus **HYSTERESIS** (black dashed line).

2.5 Tab RECORDER

The RED-Scope software features a data recorder that allows the saving of **CH0**, **CH1**, **SIG** and **TEMP**. The recorded file is saved to the hard disk of the PC and can then be evaluated with a spreadsheet program.

The file that is created has four columns and as many rows as data frames were recorded. A row is structured as follows: **Date**, **time**, **CH0**, **CH1**, **SIG**, **TEMP**.

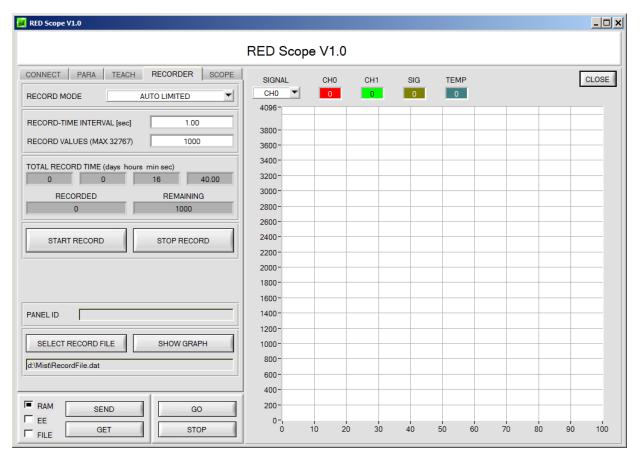

The following steps describe how data frames are recorded with the recorder:

Step 1:

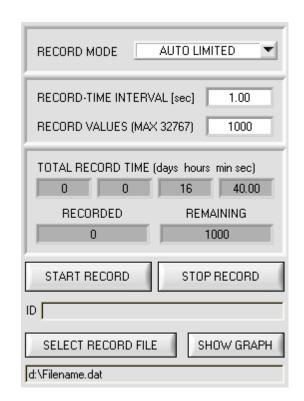

When the **RECORDER** button is pressed, the following window will be displayed:

When the **SHOW GRAPH** button is pressed, a panel will be displayed that allows the user to monitor the different signals.

The individual signals can be activated from the **SIGNAL** drop-down menu.

Step 2:

If you want to automatically record several data frames, please select **AUTO LIMITED** under **RECORD MORE**. Enter a time interval for recording under **RECORD-TIME INTERVAL [sec]**, in this example: 1, i.e. a new value is called from the sensor every second).

Then enter the maximum number of values you wish to record in the **RECORD VALUES [MAX 32767]** field.

Please note: Recording can also be stopped earlier by clicking **STOP RECORD**, the data recorded so far will not be lost.

The **TOTAL RECORD TIME** field indicates how long recording will take (in days, hours, minutes, and seconds) if all data are recorded.

Step 3:

By pressing the button **SELECT RECORD FILE** a file can be selected in which the data frame will be stored. If you select an already existing file name, you will be asked whether you want to overwrite the existing file or not.

Step 4:

Pressing the START RECORD button starts automatic data recording.

The recorder starts to record data, and the button **START RECORD** is red to indicate that recording is active. The respective data frames are shown in the display windows.

In the two display fields **RECORDED** and **REMAINING** you can check how many data frames have been recorded, and how many frames remain to be recorded.

Please note:

During recording the two input fields RECORD-TIME INTERVAL and VALUES TO BE RECORDED are inactive.

Step 5:

When as many data frames as set under **RECORD VALUES [MAX 32767]** have been recorded, or when the **STOP AUTO RECORD** button is pressed, a pop-up window will appear which confirms that the file is stored.

If you want to record an unlimited number of data, select the **AUTO UNLIMITED** function under **RECORD MORE**. Then select the desired recording interval and press **START RECORD**.

If you want to record data "manually", select the **MANUAL RECORDING** function under **RECORD MORE**. You can start reading data from the sensor by pressing the **GO** button. These data are visualised in the display window. Pressing the **CAPTURE DATA FRAME** button saves a data frame in the file that was selected under **SELECT RECORD FILE**. The **RECORDED** field shows the sum of the frames already recorded.

Please note:

When you select a file with SELECT RECORD FILE this file is created as a new file. Then a file header with the meaning of the individual columns is written to the file.

When data are then recorded, these data are appended to the selected file, even when data recording is stopped and then resumed again.

2.6 Tab SCOPE

The SCOPE tab visualises an oscilloscope.

A click on **GET CYCLE TIME** displays the current sensor scan frequency in **[Hz]** and **[ms]**. The current scan frequency must be determined for the correct calculation of **deltaX[ms]**. Please give the sensor 8 seconds to determine the correct scan frequency before you click on **GET CYCLE TIME**.

In TRIGGER MODE = SINGLE SHOT a click on SCAN records a data frame and displays it in the graph.

In **TRIGGER MODE = FALLING EDGE** and **RISING EDGE** a click on **SCAN** starts triggered recording. A trigger start can be defined with **TRIGGER LEVEL**.

In TRIGGER MODE= INTERN OUT0 recording starts stand-alone once OUT0 is out of tolerance.

In TRIGGER MODE= EXTERN IN0 recording can be started external via input IN0.

SCAN-RATE can be used to delay or accelerate recording. This corresponds with the TIMEBASE function known in oscilloscopes. **PRE TRIGGER VALUES** can be used to define how many values should still be displayed before the actual trigger start.

The zoom function in the graph can be activated by holding the control key (CTRL) and drawing a window with the mouse

A click on **ZOOM 1:1** cancels the zoom function again.

The two orange cursors can be moved with the mouse. The displays **deltaX[ms]**, **deltaY[digit]**, and **deltaY[V]** will be updated.

deltaX[ms] shows the time between the cursors in X direction.

deltaY[digit] or deltaY[V] shows the difference between the two cursors in Y direction in digits or in Volt.

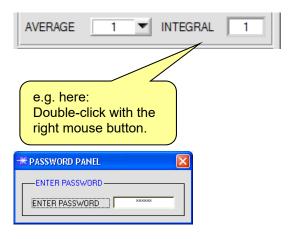

PRINT SCOPE GRAPH prints the current screen together with the text in the COMMENT text field.

The graph at the bottom shows the states of the two outputs OUT0 and OUT1 and of the inputs IN0 and IN1.

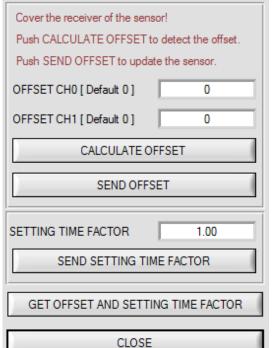

2.7 Offset Calibration

To avoid an increase of the electronic offset when using the integral function (**INTEGRAL** parameter), this offset can be eliminated by way of offset calibration or zero-point calibration. The corresponding tab is password-protected to prevent inadvertent incorrect settings.

Offset calibration can be accessed by double-clicking with the right mouse button exactly at the frame below **INTEGRAL** in the **PARA** tab.

You will then be prompted to enter a password. The password is: mellon

Then follow the instructions provided in the tab.

ATTENTION!

With offset calibration it is of utmost importance that the receiver does not see any extraneous light.

Therefore cover the receiver of the sensor, e.g. with a black cloth that is impermeable to light.

This is absolutely necessary for proper and perfect offset calibration.

Now press **CALCULATE OFFSET**. The offset value always should be clearly less than 100.

With **SEND OFFSET** this value is written to the sensor's EEPROM.

GET OFFSET AND SETTING TIME FACTOR can be used to check the value that is saved as the offset value.

If necessary, **SEND OFFSET** can be used to save an offset value manually. (! not recommended !).

SETTING TIME FACTOR is a value that is defined when the sensor is manufactured.

For sensors with an infrared light source this value is 2.5.

For all other sensors this value should be 1.0.

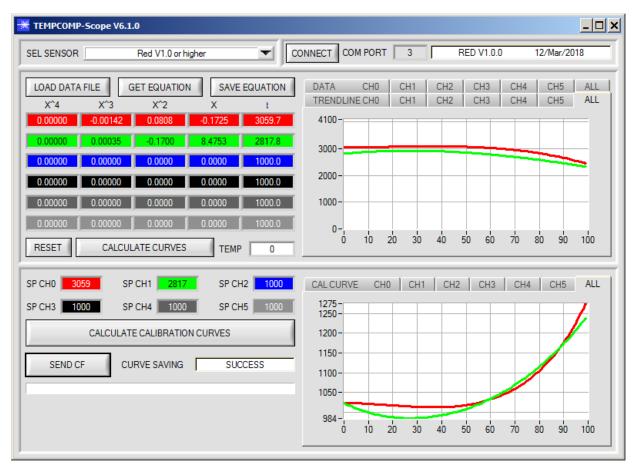

It is possible to change this value, but for safety reasons the procedure to change this value is not described in this manual. If it should be necessary to change this value, please contact your supplier.

3 Operation of the TEMPCOMP-Scope software

If a firmware update should go wrong and the temperature characteristics that are stored in the EEPROM should be lost, these characteristics must be created anew. For this purpose you will need a file with the corresponding data. This file can be obtained from your supplier.

To perform temperature compensation please start the corresponding **TEMPCOMP-Scope software** that is included on the supplied CD. Please make sure that you have a functioning sensor connection. It may be necessary to select the connection with **CONNECT**. Set the correct sensor under **SELECT SENSOR**, if this is not done automatically.

- Step 1: Load the temperature compensation file that you have received from your supplier with **GET EQUATION** or **LOAD DATA FILE**.
- Step 2: Press **CALCULATE CURVES** to display the data in the graph.
- Step 3: Select the sensor-internal operating temperature (not in °C) that the sensor has at an ambient temperature of 20°, if this has not already been done automatically. The value should be included in the file designation.
- Step 4: Press CALCULATE CALIBRATION CURVES to calculate the mean straight line.
- Step 5: Pressing the SEND CF button saves the mean straight lines in the EEPROM of the sensor.
- Step 6: Temperature compensation is successfully finished if the **SUCCESS** status message is then displayed.

Comment! If you do not immediately have the temperature compensation file at hand, simply start the **TempComp-Scope software**. Establish a connection, if it is not already established, and simply press **SEND-CF**. The sensor then functions as before, but it is not temperature-compensated.

Connector assignment of the RED sensors 4

Connection of RED to PC:

4-pole M5 fem. connector (type Binder 707) RED/PC-RS232 Pin No.: Assignment: +24VDC (+Ub) 0V (GND) 2 3 Rx0 4 Tx0

Connecting cables to choose from:

cab-las4/PC-...

cab-4/USB-...

cab-4/ETH-...

Connection of RED to PLC:

	8-pol. Buchse (Typ E <i>RED/SPS</i>	•		7		
Pin No.:	Color of wire: (cab-las8/SPS)	Assignment:				
1	white	0V (GND)				
2	brown	+24V (± 10 %)				
3	green	IN0 (Digital 0: 0 1V, Digital 1: +Ub – 10%)				
4	yellow	IN1 (Digital 0: 0 1V, Digital 1: +Ub – 10%)				
5	grey	OUT0 (Digital 0: 0) 1V, Digital 1: +Ul	b – 10%)		
6	pink	OUT1 (Digital 0: 0 1V, Digital 1: +Ub – 10%)				
7	blue	Not connected				
8	red	ANALOG (010V or 420mA)				

Connecting cable: cab-las8/SPS-...

5 RS232 communication protocol

The sensors of the RED series operate with the following **parameters** that are sent to the sensor or read from the sensor in the stated sequence.

Info! 2 bytes (8bit) are one word (16bit).

			TABLE PARAMETER
	Parameter	Type	Meaning
Para1:	POWER MODE	Word	Transmitter mode: STATIC, DYNAMIC coded to (0, 1)
Para2:	POWER	Word	Transmitter intensity channel 0 (01000) Attention intensity in thousendth!
Para3:	DYNWIN LO	Word	Low limit for dynamic window when POWER MODE=dynamic (04095)
Para4:	DYNWIN HI	Word	High limit for dynamic window when POWER MODE=dynamic (04095)
Para5:	LED MODE	Word	Control for the internal light source DC, AC coded to (0,1)
Para6:	GAIN	Word	Amplification of the integrated receiver AMP1, AMP2, AMP3, AMP4, AMP5, AMP6, AMP7, AMP8, AMP1234, AMP5678, AMP1357, AMP2468 coded to (1, 2, 3, 4, 5, 6, 7, 8,9,10,11,12)
Para7:	AVERAGE	Word	Signal averaging 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384 or 32768
Para8:	INTEGRAL	Word	Signal integration (1250)
Para9:	EVALUATION MODE	Word	Evaluation Mode CH0, CH1, CH0-CH1, CH1-CH0, (CH0+CH1)/2, CH0/(CH0+CH1), CH1/(CH0+CH1) coded to (0,1,2,3,4,5,6)
Para10:	ANALOG OUTMODE	Word	Function of the analog output: OFF, U, I coded to (0,1,2)
Para11:	ANALOG RANGE	Word	Function of the analog range: FULL, MIN-MAX, when IN0, coded to (0,1)
Para12:	ANALOG OUT	Word	Function of the analog out: CONT, RISING EDGE of IN1 coded to (0,1)
Para13:	DIGITAL OUTMODE	Word	Function of the digital output: OFF, DIRECT, INVERSE coded to (0,1,2)
Para14:	HOLD	Word	Hold time for minimum pulse length coded to (0100 [ms]) send value*10
Para15:	DEAD TIME	Word	Dead Time in [%] coded to (0100)
Para16:	INTLIM CH0	Word	Intensity limit CH0 coded to (04095)
Para17:	INTLIM CH1	Word	Intensity limit CH1 coded to (04095)
Para18:	THRESHOLD MODE	Word	Select Threshold Mode LOW, HI, WIN coded to (0,1,2)
Para19:	THRESHOLD TRACING	Word	Select Threshold Tracing OFF, ON TOL, ON CONT coded to (0,1,2)
Para20:	TT UP	Word	Time delay for Threshold Tracing Up (060000)
Para21:	TT DOWN	Word	Time delay for Threshold Tracing Down (060000)
Para22:	EXTERN TEACH	Word	External teach mode: OFF, DIRECT, DYN, MAX, MIN, (MAX-MIN)/2+MIN coded to (0,1,2,3,4,5)
Para23:	THRESHOLD CALC	Word	Threshold Calculation ABSOLUTE (digit), RELATIVE (%) coded to (0,1)
Para24:	TEACH VALUE	Word	Teach Value (Reference) for threshold calculation (04095)
Para25:	TOLERANCE	Word	Tolerance Value for threshold calculation (04095)
Para26:	HYSTERESIS	Word	Hysteresis Value for threshold calculation (04095)

Upon request, the data acquired and processed by the sensor are sent by the sensor in the following sequence.

	TABLE DATA VALUE										
DAT	A VALUE	Type	Meaning								
DatVal1:	CH0	Word	Analogue raw signal of the receiver channel 0								
DatVal2:	CH1	Word	Analogue raw signal of the receiver channel 1								
DatVal3:	TEMP	Word	Sensor internal temperature (not in °C or F)								
DatVal4:	REF	Word	Reference value for threshold calculation								
DatVal5:	SIG	Word	Evaluation Signal								
DatVal6:	MIN	Word	Minimum value of SIG during IN0 was HI								
DatVal7:	MAX	Word	Maximum value of SIG during IN0 was HI								
DatVal8:	DIGITAL IN	Word	Bit 0 is 0 when IN0 is LO								
			Bit 0 is 1 when IN0 is HI								
			Bit 1 is 0 when IN1 is LO								
			Bit 1 is 1 when IN1 is HI								
DatVal9:	DIGITAL OUT	Word	Bit 0 is 0 when signal is out of tolerance								
			Bit 0 is 1 when signal is in tolerance								
			Bit 1 is 0 when THRESHOLD MODE = LO or HI								
			Bit 1 is 0 when THRESHOLD MODE = WIN and signal is under the window.								
			Bit 1 is 1 when THRESHOLD MODE = WIN and signal is above window.								
DatVal10:	ANALOG OUT	Word	Analogue output value								

Digital serial communication is used for the exchange of data between the software running on the PC and the sensor.

For this purpose the control unit features an EIA-232 compatible interface that operates with the (fixed) parameters "8 data bits, 1 stop bit, no parity bit, no handshake".

Five values are available for the baudrate: 9600baud, 19200baud, 38400baud, 57600baud and 115200baud. As an option the PC software also can communicate through TCP/IP or USB. In these cases transparent interface converters must be used that allow a connection to the RS232 interface.

A proprietary protocol format that organises and bundles the desired data is used for all physical connection variants between PC software and control unit. Depending on their type and function the actual data are 16- or 32-bit variables and represent integer or floating-point values. The protocol format consists of 8-bit wide unsigned words ("bytes"). The actual data therefore sometimes must be distributed to several bytes.

The control unit always behaves passively (except if another behaviour has been specifically activated). Data exchange therefore always is initiated by the PC software. The PC sends a data package ("frame") corresponding to the protocol format, either with or without appended data, to which the control unit responds with a frame that matches the request.

The protocol format consists of two components:

A "header" and an optional appendant ("data").

The header always has the same structure.

The first byte is a synchronisation byte and always is 85_{dez} (55_{hex}).

The second byte is the so-called order byte. This byte determines the action that should be performed (send data, save data, etc.).

A 16-bit value (argument) follows as the third and fourth byte. Depending on the order, the argument is assigned a corresponding value.

The fifth and sixth byte again form a 16-bit value. This value states the number of appended data bytes. Without appended data both these bytes are 0_{dez} or 00_{hex} , the maximum number of bytes is 512.

The seventh byte contains the CRC8 checksum of all data bytes (data byte 1 up to and incl. data byte n).

The eight byte is the CRC8 checksum for the header and is formed from bytes 1 up to and incl. 7.

The header always has a total length of 8 bytes. The complete frame may contain between 8 and 520 bytes.

Byte1	Byte2	Byte3	Byte4	Byte5	Byte6	Byte7	Byte8	Byte9	Byte10	 Byte n+7	Byte n+8
Header	Header	Header	Header	Header	Header	Header	Header	Data	Data	Data	Data
0x55	<order></order>	<arg> (lo byte)</arg>	<arg> (hi byte)</arg>	<len> (lo byte)</len>	<len> (hi byte)</len>	CRC8 (Data)	CRC8 (Header)	Data1 (lo byte)	Data1 (hi byte)	 Data n/2 (lo byte)	Data n/2 (hi byte)

The following **orders** can be sent to the sensor.

Number	ORDER (header byte no. 2)	Example							
0	Sensor answers with order=0 if a communication error occurs.								
	ARG=1: Invalide order number was sent to the sensor								
	ARG=2: General communication error (wrong baudrate, overflow,)								
1	Write parameter to the RAM of the sensor								
2	Read parameter from the RAM of the sensor	order=2							
3	Load parameter and actual Baudrate from RAM to EEPROM of the sensor	order=3							
4	Load parameter from EEPROM to RAM of the sensor	order=4							
5	Read CONNECTION OK and serial number from sensor	order=5							
6	Free								
7	Read Firmware String and serial number from sensor	order=7							
8	Read data values from sensor	order=8							
105	Get cycle time from sensor	order=105							
190	Write new baud rate to the sensor	order=190							

CRC8 Checksum

The so-called "Cyclic Redundancy Check" or CRC is used to verify data integrity. This algorithm makes it possible to detect individual bit errors, missing bytes, and faulty frames. For this purpose a value - the so-called checksum - is calculated over the data (bytes) to be checked and is transmitted together with the data package. Calculation is performed according to an exactly specified method based on a generator polynomial. The length of the checksum is 8 bit (= 1 byte). The generator polynomial is:

$$X^8 + X^5 + X^4 + X^0$$

To verify the data after they have been received, CRC calculation is performed once again. If the sent and the newly calculated CRC values are identical, the data are without error.

The following pseudo code can be used for checksum calculation:

table[]

0	94	188	226	97	63	221	131	194	156	126	32	163	253	31	65

Example order=105: Get cycle time from sensor

DATA FRAME PC → Sensor

Byte0	Byte1	Byte2	Byte3	Byte4	Byte5	Byte6	Byte7
Header	Header	Header	Header	Header	Header	Header	Header
0x55	<order></order>	<arg></arg>	<arg></arg>	<len></len>	<len></len>	CRC8	CRC8
0,00		(lo byte)	(hi byte)	(lo byte)	(hi byte)	(Data)	(Header)
85 (dec)	105	0	0	0	0	170	130
		ARG=0		LEN	V= 0		

DATA FRAME Sensor → PC

Byte0	Byte1	Byte2	Byte3	Byte4	Byte5	Byte6	Byte7	Byte8	Byte9	Byte10	Byte11
Header	Header	Header	Header	Header	Header	Header	Header	Data	Data	Data	Data
0x55	<ordor></ordor>	<arg></arg>	<arg></arg>	<len></len>	<len></len>	CRC8	CRC8	lo word	lo word	hi word	hi word
0,000	<order></order>	(lo byte)	(hi byte)	(lo byte)	(hi byte)	(Data)	(Header)	lo byte	hi byte	lo byte	hi byte
85 (dec)	105	0	0	8	0	82	17	23	140	8	0
<u> </u>		AR	G=0	LEN	I=8			(CYCLE COU	NT = 56015	1

Byte12	Byte13	Byte14	Byte15				
Data	Data	Data	Data				
lo word	lo word	hi word	hi word				
lo byte	hi byte	lo byte	hi byte				
64	156	0	0				
COUNTER TIME = 40000							

Cycle Time [Hz] = CYCLE COUNT / (COUNTER TIME * 0,0001)

Cycle Time [ms] = (COUNTER TIME * 0,01) / CYCLE COUNT

Example order=190: Write new baud rate to the sensor.

DATA FRAME PC → Sensor

Byte1 Header	Byte2 Header	Byte3 Header	Byte4 Header	Byte5 Header	Byte6 Header	Byte7 Header	Byte8 Header
0x55	<order></order>	<arg> (lo byte)</arg>	<arg> (hi byte)</arg>	<len> (lo byte)</len>	<len> (hi byte)</len>	CRC8 (Data)	CRC8 (Header)
85 (dec)	190	1	0	0	0	170	14
		AR	G=1	LEI	N=0		

New baud rate is determined by argument.

ARG=0: baud rate = 9600 ARG=1: baud rate = 19200 ARG=2: baud rate = 38400 ARG=3: baud rate = 57600 ARG=4: baud rate = 115200

DATA FRAME Sensor → PC

85 (dec)	190	0	0	0	0	170	195
		AR	G=0	LEI	N=0		

A. Firmware update via software Firmware Loader

A.1 Manual software Firmware Loader V1.1

This manual describes the installation of the Firmware Loader PC software and as a support for starting up the Firmware Loader software explains the individual functional elements of the graphic Windows® user interface.

The software allows the user to perform an automatic firmware update. The update will be carried out through the RS232 interface.

An initialisation file (xxx.ini) and a firmware file (xxx.elf.S) are required for performing a firmware update. These files can be obtained from your supplier. In some cases an additional firmware file for the program memory (xxx.elf.p.S) is also needed, and this file will be automatically provided together with the other two files.

Important! For a firmware update the two or three files must always be located in the same folder.

A plausibility check is performed after the initialisation file has been loaded with the Firmware Loader. If the initialisation file was changed or damaged, it will not be possible to perform a firmware update.

When the plausibility check is successfully completed, the instructions contained in the initialisation file will be carried out step by step.

The complete memory contents of the micro-controller in the sensor will be deleted in a firmware update. This means that both the program in the program memory and the data in the data memory will be lost.

The new firmware automatically writes the correct data to the program memory again.

However, the parameter settings, temperature curves, linearization curves, etc. that are stored in the data memory (EEPROM) will be deleted.

With the Firmware Loader V1.1 the data will be saved in the EEPROM, and can be written back again after successful firmware update.

For this purpose the software creates an EEPROM backup file.

A.2 Installation of the software Firmware Loader V1.1

Hardware requirements for successful installation of the Firmware Loader software:

- IBM PC AT or compatible
- VGA graphics
- Microsoft® Windows® XP, VISTA, 7
- Serial RS232 interface at the PC
- Microsoft® compatible mouse
- Cable cab-las4/PC (cab-las5/PC) for the RS232 interface or cab-4/USB (cab-5/USB) for USB slot
- CD-ROM drive

The software can only be installed under Windows. Windows must therefore be started first, if it is not yet running. Please install the software as described below:

- 1. The software can be installed directly from the installation CD-ROM. To install the software, start the SETUP program in the INSTALL folder of the CD-ROM.
- 2. The installation program displays a dialog and suggests to install the software in the C:\"FILENAME" directory on the hard disk. You may accept this suggestion with **OK** or [ENTER], or you may change the path as desired. Installation is then performed automatically.
- 3. During the installation process a new program group for the software is created in the Windows Program Manager. In the program group an icon for starting the software is created automatically. When installation is successfully completed the installation program displays "Setup OK".
- After successful installation the software can be started with a left mouse button double-click on the icon.

Windows® is a trademark of the Microsoft Corp. VGA^{TM} is a trademark of the International Business Machines Corp.

Please read this chapter before you start!

In this example a software update is performed from SPECTRO3 V4.0 to SPECTRO3 V4.1.

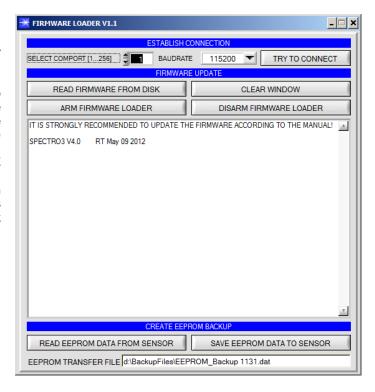

Step 1:

When the Firmware Loader software is started, this window opens on the Windows® user interface.

Immediately after starting, the software attempts to establish a connection to the connected sensor. If the sensor should not be connected at **COM PORT 1**, please select the corresponding **COM PORT**.

Please make sure that the correct **BAUDRATE** is selected.

Now try to establish a connection by clicking on **TRY TO CONNECT**. When the connection has been established, the sensor sends back information about the current firmware.

Step 2:

Press the **READ FIRMWARE FROM DISK** button and load the **xxx.ini** file.

The uploaded initialization file will be displayed in the status window.

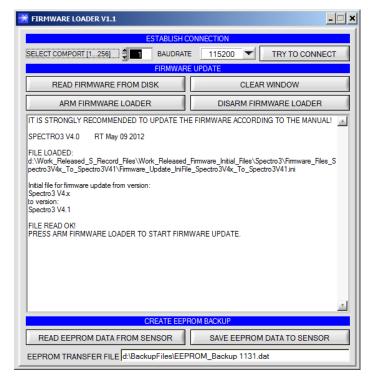

As described above, a plausibility check of the initialisation file will be performed first.

If the file is OK, the following message will be displayed:

File read OK!

Press **ARM FIRMWARE LOADER** to start the firmware update.

Please read the comments that are shown in the display window. These comments allow you to make sure that you have loaded the correct initialisation file.

Step 3:

Now click on the **ARM FIRMWARE LOADER** button. The program now attempts to send a software command that interrupts the normal program run and jumps to the start address of the boot sector.

If this is successful, the sensor displays a prompt for loading the S-Record file to the sensor.

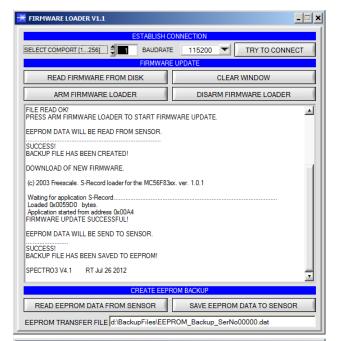

When you press the **ARM FIRMWARE LOADER** button the firmware update will be performed automatically.

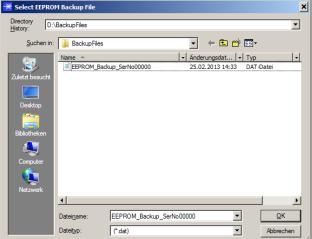

In the course of the update process you will only be prompted to enter a name for the EEPROM backup file. If the firmware update should run perfectly until the EEPRM data are read out, but should then go wrong for any reason whatsoever, the EEPROM backup file can always be written back with SAVE EEPROM DATA TO SENSOR.

The file name for your **EEPROM** backup file should be chosen such that the names for several sensors cannot be mixed up. Using a file name that contains the sensor serial number might be advisable. Saving this file for future updates also might be a good idea.

After a successful update the sensor displays the status line of the new firmware.

The complete update process may take up to 1 minute.

If, contrary to expectations, there should be any trouble with the update of the program memory, it will still be possible to perform an update, even though it may look like the sensor was "killed".

Please make sure that you have selected the correct **COM PORT** and the correct **BAUDRATE**.

You will not get any connection when you click on **TRY TO CONNECT**.

Load the corresponding **xxx.ini** file from the hard disk.

Then click on the **ARM FIRMWARE LOADER** button.

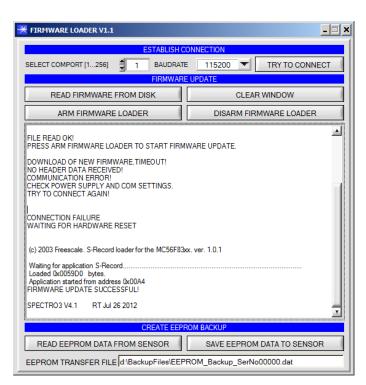

The program will try to send the software command for the update. This will not work, however, and you will get a **CONNECTION FAILURE** message.

However, the Firmware Loader software now is "armed" for 30 seconds.

If you perform a hardware reset within these 30 seconds, the firmware update will be performed.

After a successful update the sensor displays the status line of the new firmware.

The complete update process may take up to 1 minute.

INFO! In case that the sensor was "killed", the sensor will work with a BAUDRATE of 115200.

You may at any time create an EEPROM backup file for archiving it on your hard disk.

To do this, click on **READ EEPROM DATA FROM SENSOR**. You will be prompted to chose an initialization file in case that there has not yet been loaded any. Afterwards you will be asked to enter a file name. The selected name will be shown in the **EEPROM TRANSFER FILE** display.

The file name for your **EEPROM** backup file should be chosen such that the names for several sensors cannot be mixed up. Using a file name that contains the sensor serial number might be advisable.

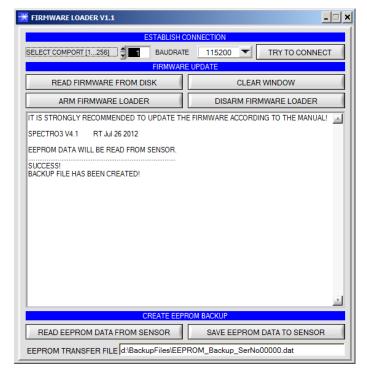

The Firmware Loader then reads all the EEPROM data from the data memory and saves these data in the selected file.

Upon successful completion the following message will be displayed:

Success!

Backup File has been created!

If something should go wrong in a firmware update, any you have created the **backup file**, the saved **EEPROM backup file** can at any time be uploaded to the sensor again with **SAVE EEPROM DATA TO SENSOR**.

CLEAR WINDOW resets the display window.

If you should not get any response for a longer time, or if messages should be displayed in the status line, **DISARM FIRMWARE LOADER** can be used to cancel the firmware update process.

However, you should always wait for approx. 1 minute before you press this button.
